## PROPER GUTTER AND DOWNSPOUT SIZING

DESIGN OF ROOF DRAINAGE SYSTEMS ROOF DRAINAGE

The roof is one of the most essential parts of a building as it
protects occupants, contents, and interior of the structure from the elements. Once an architect has determined the kind of roof he intends to use, he must give equal attention to the design of the roof drainage system.

Factors to be considered in the design of roof drainage systems
are the area to be drained, size of gutters, downspouts, outlets, slope of roof, type of building, and appearance.

## ROOF AREA TO BE CONSIDERED

The design capacity for a roof drainage system depends on The quantity of water to be handled. The quantity of water in
turn depends on the roof area, slope, and rainfall intensity.
In considering the roof area, it must be remembered that rain does not necessarily fall vertically and that maximum conditions exist only when rain falls perpendicular to a surface.
Since the roof area would increase as its pitch increases, then it would not be advisable to use the plan area of a pitched
roof in the calculation of a drainage system.
Experience has taught that use of the true area of a pitched roof often leads to oversizing of gutters, downspouts, and drains. To determine the design area for a pitched roof, Table
$1-1$ is used.
TABLE 1-1 DESIGN AREAS FOR PITCHED
ROOFS

|  | PITCH |  | ** |
| :---: | :--- | :--- | :--- |
| in./ft. |  | $\mathrm{mm} / \mathrm{mm}$ |  |
| Level to 3 | $76 / 305$ | 1.00 |  |
| 4 to 5 | $102-$ | 1.05 |  |
| $127 / 305$ |  | 1.10 |  |
| 6 to 8 |  |  | 1.20 |
| $203 / 305$ |  | 1.30 |  |
| 9 to 11 | $229-$ |  |  |
| $279 / 305$ |  |  |  |
| 12 |  | $305 / 305$ |  |

To determine the design area multiply the plan area by the factor in B column

These areas are then divided by the proper factor given in Table 1-2, thus obtaining the required area in square inches
(square mm) for each downspout. From Table 1-3 select the
downspout.

## PROPER GUTTER AND <br> DOWNSPOUT SIZING

Rainfall intensity is usually given in inches per hour for a five minute duration or one hour duration based on U.S. Weather Bureau records. Table 1-2 based on records through 1978, gives five minute intensities for selected cities. New Orleans, Los Angeles, for example, may have $8 \mathrm{in} . / \mathrm{hr}$. $203 \mathrm{~mm} / \mathrm{hr}$ ) for a five minute duration yet record only 4.8 in . ( 121 mm ) in an hour over a 100 year period. These rates correspond to $0.133 \mathrm{in} . / \mathrm{min} .(3.4 \mathrm{~mm} / \mathrm{min}$.) and $0.08 \mathrm{in} . / \mathrm{min} .(2 \mathrm{~mm} / \mathrm{min}$.). Local codes may require that drainage systems only be designed for the latter. It takes 96.15 square feet( 8.93 square meters) of surface with 1 inch per hour $(25 \mathrm{~mm} / \mathrm{hr}$ ) of water to correspond with $1 \mathrm{gpm}(0.063 \mathrm{l} / \mathrm{s})$ flow rate. Downspouts and gutters are sized in relation to rainfall on this basis.

Plumbing codes typically use the vertically projected roof area for drainage design and they often use a square foot allowance per square inch of downspout for 1 in ./hr.(25 $\mathrm{mm} / \mathrm{hr}$ ) rainfall that varies with diameter, for example, 3 in. $(76 \mathrm{~mm})$ : 911 ( 85 ); $4 \mathrm{in} .(102 \mathrm{~mm}): 1100$ (102); 5 in. $(127 \mathrm{~mm})$ : 1280 (119); 6 in. $(152 \mathrm{~mm})$ : 1400 (130) and 8 in. $(203 \mathrm{~mm})$ : 1750 (163) sq. ft.(sq. m). Net drainage capacity from using Table 1-1 and 1-2 should be compared with local code requirements.

## DOWNSPOUT SIZING

In sizing downspouts, the following considerations apply:

1. Downspouts of less than 7.00 sq in. $(4515 \mathrm{sq} \mathrm{mm})$ cross section should not be used except for small areas such as porches and canopies.
2. The size of the downspout should be constant throughout
its length.
3. Downspouts should be constructed with conductor heads every $40 \mathrm{ft}(12.2 \mathrm{~m})$ to admit air and prevent vacuum.
4. Offset of more than $10 \mathrm{ft}(3.0 \mathrm{~m})$ can affect drainage capacity.

5 . The gutter outlet capacity should suit the downspout capacity.
6. The downspout size must suit the bottom width of the gutter.

See Figures 1-31 and 1-32 for gage
7. Assuming that using the fewest number of downspouts is desirable, their locations will be affected by
a. gutter capacity and length. To limit the effects of thermal expansion in gutters $50 \mathrm{ft}(15.3 \mathrm{~m})$ is a practical maximum length of gutter to be served by a downspout. Unless special provisions are made for flexibility in downspouts, gutters and their support systems, gutters should expand away from downspouts and downspouts should not be located
near gutter expansion joints. See expansion coefficients
in Appendix A-1 and expansion allowances in Figures 1-5 to 1-10.
b. the capacity of the inlet tube. See Table 1-3 and Figure

1-33. Also, a sharp bend at the inlet may clog.
c. potential for water freezing in downspouts and gutters.

Open, partially open or corrugated styles downspouts
are suggested for areas subject to icing. Locating
downspouts
on the north side of buildings is not recommended
for such areas.
d. the appearance of the downspout system and a potential need for concealment. See Figures 1-31 and 1-32.
e. the greater capacity of a pitched gutter.
f. the downspout discharge location. Water disposal at
this location should be acceptable. See Figures 1-31 and 1-36.
g. the risk of gutter overflow from insufficient drainage
capacity. See Figures 1-4, 1-21, and 1-23.
h. a scupper serving a designated roof area. See Figures

1-26 to 1-30.
After the number and location of downspouts have been determined, the areas to be drained by each downspout should be figured. In making this calculation for a pitched roof, the plan area should be adjusted according to recommendations
given on Table 1-1.
SAMPLE PROBLEM: Select downspouts for a building in Boston, Mass. The building is $100 \times 85 \mathrm{ft} .(30.5 \times 26 \mathrm{~m})$ with a double pitched roof having a slope of $6 \mathrm{in} . / \mathrm{ft} .(152 \mathrm{~mm} / \mathrm{m})$. The slope is toward the 100 ft . $(30.5 \mathrm{~m})$ side. Maximum rainfall
conditions will be used to determine downspout size.
It is decided to drain the building with 4 downspouts located
at each corner of the building. An expansion joint will be installed in each gutter between the downspouts.

The plan area of this building is 8500 sq ft . $(790 \mathrm{sq} \mathrm{m})$. Since
the slope is $6 \mathrm{in} . / \mathrm{ft}$. $152 \mathrm{~mm} / \mathrm{m}$ ), factor 1.10 is used (Table $1-1)$, making the design area 9350 sq ft . 868 sq m ). Thus each of the four downspouts will serve a 2338 sq ft . 217 sq m ) area. From column B, Table 1-2, opposite Boston, it is found that 1 sq in . 645 sq mm ) of downspout will drain 170 sq ft . 16 sq m ) of roof area. Divide 2338(217) by 170(16) to determine that each downspout should have a minimum area
of $13.56 \mathrm{sq} \mathrm{in.(8746} \mathrm{sq} \mathrm{mm})$.
From Table 1-3, it is found that there is a choice of; a 5 in . (127 mm) Plain Round, a 5 in . $(127 \mathrm{~mm}$ ) Corrugated Round,
a $5 \mathrm{in} .(127 \mathrm{~mm})$ Rectangular Corrugated, or $5 \mathrm{in} .(127 \mathrm{~mm})$
Plain Rectangular downspout.

## GUTTER SIZING

In sizing gutters, the following considerations apply for typical
section lengths of 8 to 10 feet( 2.41 to 3.0 m ):

1. Spacing and size of outlet openings. (The gutter can never
be any more effective than the outlet and downspout selected
to drain it. Downspout sizes must not exceed the bottom width of the gutter.)
2. Slope of the roof. (The gutter must be of such a design and location that water from a steep pitched roof will not by its own velocity tend to overrun the front edge.)
3. Style of gutters to be used. (All gutters are not effective for their full depth and width, see Figures 1-1 and 1-4 for design data.)
4. Maximum length of gutter. ( 50 ft . $(15.2 \mathrm{~m}$ ) between ends or expansion joints is the limit unless the system is especially
designed to accommodate the greater expansion, the larger flow and the need for special supports.) 5. Gutter support capability. (Supports should be based on full capacity of the gutter. Ice load capacity also affect the size and strength of the system.)

Level gutters may be sized by Charts 1-1, 1-2, or 1-3. Sloped gutters may be sized by Chart 1-3. Formulae for flow in gutters
with different pitch are not available. The capacity of a gutter with $1 / 16 \mathrm{in} . / \mathrm{ft} .(5.21 \mathrm{~mm} / \mathrm{m})$ or less pitch is taken as that of a level gutter even though it is somewhat greater.

## RECTANGULAR GUTTER SIZING

The size of rectangular gutters depends upon these factors:

1. Area to be drained. (A, Chart 1-1)
2. Rainfall intensity per hour. (I, Chart 1-1)
3. Length of gutter in ft . m ) ( L, Chart 1-1)
4. Ratio of depth to width of gutter. (M, Chart 1-1)

Chart $1-1$ is based on level gutter capacity as experimentally
determined by the National Institute of Standards and Technology
(NIST) formerly National Bureau of Standards. It is plotted from $\mathrm{W}=0.0106 \mathrm{M}-4 / 7 \mathrm{~L} 3 / 28(1 \mathrm{~A}) 5 / 14$ with W in feet(m).
IRREGULAR CROSS SECTION GUTTER SIZING
The required sizes of gutters other than rectangular or round
can be determined by finding the semicircle or rectangular area that most closely fits the irregular cross section.

## HALF ROUND GUTTER SIZING

Chart 1-2 is based on level gutter capacity as determined by
NIST. It is based on $\mathrm{W}=0.0182(\mathrm{IA}) 2 / 5 . \mathrm{W}$ is the width in in. $(\mathrm{mm}$ ). I denotes rainfall intensity (Table $1-2$ ) and $A$ is the roof area in square feet(sq m) (Table 1-1).

SAMPLE PROBLEM: To size rectangular gutter for a building
$120 \times 30 \mathrm{ft}$. $(35.6 \times 9.1 \mathrm{~m})$ located in Buffalo, NY. This
building has a flat roof with a raised roof edge on three sides.
A gutter is to be located on one of the 120 ft . $(35.6 \mathrm{~m})$ sides.
So that each section of gutter will not exceed 50 ft .(15.2 m),
three downspouts will be used with 2 gutter expansion joints.
The area to be drained by each section of gutter will be 1200
sq ft .(111.5 sq m), the rainfall intensity from Table 1-2, col A
is $6 \mathrm{in} / \mathrm{hr}(152 \mathrm{~mm} / \mathrm{hr})$, the length of each gutter section is $40 \mathrm{ft} .(12.2 \mathrm{~m})$, and the ratio of gutter depth to width is 0.75 .
On Chart 1-1 find the vertical line representing $L=40(12.2$
$\mathrm{m})$. Proceed vertically along this line to its intersection with
the oblique line representing $M=0.75$. Pass to $B$ vertically to the intersect the horizontal line representing $\mathrm{IA}=$ 7200 (16948). The point of intersection occurs between the oblique line representing gutter widths of 5 and 6 in .(127 and 152 mm ). The required width of gutter is, therefore, 6 in. $(152 \mathrm{~mm})$ and its depth need be only 4.5 in . $(114 \mathrm{~mm})$.in.

SAMPLE PROBLEM: To size a half round gutter for a building,
located in Kansas City, Mo., with a flat roof $80 \times 40$
ft . $(24.4 \times 12.2 \mathrm{~m})$. This building has a parapet wall on three sides and a gutter to be located on an 80 ft . 24.4 m ) side.
Column A, Table 1-2, was used to determine rainfall conditions.
Since the gutter run will exceed 50 ft . 15.2 m ), two downspouts will be used with an expansion joint between.

The area of the building is 3200 sq ft . ( 297 sq m ). Thus each
of the downspouts will serve an area of $1600 \mathrm{sq} \mathrm{ft}. \mathrm{(149} \mathrm{sq}$
m). From column A, Table 1-2, opposite Kansas City, Mo., it
is found that 1 sq in. ( 100 sq mm ) of downspout will drain 160 sq ft ( $2.3 \mathrm{sq} \mathrm{m} / 100 \mathrm{sq} \mathrm{mm}$ ) of roof area. Divide 1600 sq
ft . ( 149 sq m ) by $160 \mathrm{sq} \mathrm{ft/sq} \mathrm{in}. \mathrm{( } 2.3 \mathrm{sq} \mathrm{m} / 100 \mathrm{sq} \mathrm{mm}$ ) to determine that each downspout should have a minimum area
of 10 sq in . (6470 sq mm). From Table 1-3 it is found that a4
in. ( 102 mm ) downspout is required. From Chart $1-2$ it is determined that a 9.5 in . $(241 \mathrm{~mm})$ half round gutter should be used. Area and flow in Table 1-4 are based on 1 in . (25 mm ) of rainfall per hour; divide these areas by the local rainfall
rate in inches per hour to determine the actual roof area to be served by the gutter diameter. "The capacity of a sloped
rectangular gutter may be approximated by using a gutter cross section area not less than that of a semicircular gutter
and a depth to width ratio of at least 0.75 .

## PROPER GUTTER AND DOUNSPOUT SIZING

CHART 1-1
WIDTH OF RECTANGULAR GUTTERS FOR GIVEN ROOF AREAS AND RAINFALL INTENSITIES

$I A=$ RAINFALL INTENSITY $\times$ AREA (AREA FROM TABLE 1-1 THAT RELATES TO L)

## PROPER GUTTER AND DOWNSPOUT SIZING
